# Guide to LBE exercises

Michael Seaton  
UKRI STFC Daresbury Laboratory  
[michael.seaton@stfc.ac.uk](mailto:michael.seaton@stfc.ac.uk)

# Mesoscale exercises

## Put together practical exercises on DPD and LBE

- Available via main CCP5 Summer School exercises page:  
[summer.ccp5.ac.uk](http://summer.ccp5.ac.uk)
  - Points to Jupyter notebooks for each exercise, available to download using Google Colab to run on your laptops
  - Requirements to use notebooks: Fortran/C/C++ compilers, GNU Make, Python and modules, VMD, ParaView
- DPD Exercises available as Day 9
- LBE Exercises available as Day 10 and Day 11
- Additional background information on exercises, theory and brief C programming guide (needed for LBE exercises)
- Download link to these slides on the LBE exercises and similar ones for the DPD exercises

# Mesoscale exercises

The screenshot shows a web browser displaying the CCP5 Summer School website. The page title is "CCP5 Summer School: Methods in Molecular Simulation". The left sidebar lists the following items: "CCP5 Summer School 4.0.0 documentation", "Day 1-2", "Day 3", "Day 4", "Day 5", "Day 6", "Day 8", "Day 9-11", and "Appendix". The main content area lists exercises, with three items highlighted by blue boxes:

- Day 9: Setup environment for advanced courses
- Advanced: Mesoscale Modelling
- Appendix B: The Boltzmann Equation - an outline derivation

Annotations on the right side of the image provide context for these highlighted items:

- "Page on setting up connection to SCARF" points to the "Day 9: Setup environment for advanced courses" box.
- "Starting page for DPD and LBE Tutorials" points to the "Advanced: Mesoscale Modelling" box.
- "Additional theoretical information on LBE and fluid mechanics" points to the "Appendix B: The Boltzmann Equation - an outline derivation" box.

At the bottom of the page, the footer text reads: "© Copyright 2017-2024, CCP5. Created using Sphinx 8.1.3. and Sphinx-Immaterial".

# LBE Jupyter notebooks

The screenshot shows a web browser window with the address bar displaying the local file path: `wsl.localhost/Ubuntu/home/srb73435/Codes/summerschool/build/html/WORKSHOP/Day_10Meso/Day10LBETutorial1.html`. The page title is "LBE Tutorial Exercise 1: Single component LBE simulations". The left sidebar contains a navigation menu for the "CCP5 Summer School 4.0.0 documentation", with "Day 10 Mesoscale: LBE Tutorial Exercise 1: Single component LBE simulations" selected. The main content area features a heading "LBE Tutorial Exercise 1: Single component LBE simulations" and a paragraph explaining the two-dimensional LBE code. A blue box highlights an "Open in Colab" button. The right sidebar contains a "Table of contents" with links to various exercises. The footer of the page includes the UKRI Science and Technology Facilities Council logo.

LBE Tutorial Exercise 1: Single component LBE simulations

We are going to work with a simple two-dimensional LBE code written in C, `CCP5_01.c`, which applies single-relaxation-time Bhatnagar-Gross-Krook (BGK) collisions, i.e. LBE with BGK or **LBGK**. This code will carry out LBE over a certain number of timesteps and write out files with results for the final calculation timestep.

The `data_density.csv` and `data_density.dat` files print the fluid density  $\rho(x, y)$  at each grid point, while the `data_stfn.csv` and `data_stfn.dat` files print a scalar stream function,  $\psi(x, y)$ , which can be used to plot lines where flow speeds are constant. (More details about stream functions can be found in our [Outline Notes on Fluid Mechanics](#).) The two sets of files are in different formats: the files with comma-separated values (CSV) can be read into spreadsheet programs or used with our Python plotting scripts, while the other files are formatted using fixed-length delimiting and can be read into e.g. Gnuplot.

The system we are modelling with this code - 2D flow inside a square 'lid-driven' cavity (illustrated in Figure 1) - is described in more detail [here](#). We are going to ask you to make some modifications to this code for some of the exercises: if you are not entirely familiar with C, we have some hints on how to make modifications to codes written in this language in [our](#)

Table of contents

Ex1. Code familiarisation/concepts from theoretical fluid mechanics

Checks

Stability

Reynolds' number variation

Dynamic similarity

Time-marching and steady-state flow

Ex2. Manipulation of boundary conditions for complex flow

Ex3. Computational Efficiency

Ex4. A fix for incompressible Navier-Stokes' fluids

Ex5. The viscous stress tensor

# LBE practical exercises

## Designed to show LBE's capabilities as a mesoscale modelling method

- Two tutorials (notebooks covering multiple exercises):
  1. Single-component LBE simulations (lid-driven cavity)
    - Code familiarisation/concepts from theoretical fluid mechanics
    - Manipulation of boundary conditions for complex flow
    - Computational efficiency
    - Fix for incompressible Navier-Stokes' fluids
    - Viscous stress tensor
  2. Multi-component LBE simulations (suspended drop)
    - Code familiarisation, Laplace law validation, fluid component segregation, curvature calculations
    - Code transformation, equilibration dynamics, algorithm change
- All but last notebook use custom codes written in C, last notebook uses DL\_MESO\_LBE

# Tutorial Exercise 1: Single component LBE simulations

## Ex1. Code familiarisation/concepts from theoretical fluid mechanics

- Notebook: [Day10LBETutorial1.ipynb](#)
- Introduces a simple LBE code in C: `CCP5_01.c`
  - Includes a command-line option for required number of timesteps
  - Models a 2D ‘lid-driven cavity’ system
  - On-site bounce-back for side and bottom walls
  - Equilibrium forcing for top moving wall at speed  $U_0$
  - Additional lattice points above top wall to prevent interference between top and bottom boundaries – have no effect on system itself and thus discarded

# Tutorial Exercise 1: Single component LBE simulations

## Ex1. Code familiarisation/concepts from theoretical fluid mechanics

- Need to compile before running code using (GNU) C compiler:

```
gcc -o LBE CCP5_01.c
```

- Run code with command-line option for number of timesteps ( $N$ ):

```
./LBE N
```

- Defaults to 4000 timesteps if  $N$  not specified
- Python script available to launch code and display progress bar in Jupyter notebook
- Top of code has `#define` statements and a variable declaration setting simulation properties (size of lattice, initial fluid density, speed of top wall  $U_0$ , relaxation frequency  $\omega$ )
  - **Changing any of these requires re-compilation to take effect!**

# Tutorial Exercise 1: Single component LBE simulations

## Ex1. Code familiarisation/concepts from theoretical fluid mechanics

- Code generates ‘snapshot’ files with fluid densities and constant-velocity stream functions  $\psi$  at all grid points (apart from discarded region above wall)
  - Python scripts available to read files and plot data in notebook
  - Also have MATLAB/Octave and Gnuplot plotting scripts
- Sub-exercises:
  - Calculational stability when varying Reynolds’ number:

$$Re = \frac{U_0 L_y}{\nu}$$

- Dynamic similarities in solutions for same  $Re$  but different system sizes, relaxation frequencies and/or wall speeds
- How simulation gets to a steady state (number of required timesteps)

# Tutorial Exercise 1: Single component LBE simulations

## Ex2. Manipulation of boundary conditions for complex flow

- Default boundary condition for stationary walls is on-grid bounce-back
- `CCP5_01.c` also has code to use mid-grid bounce-back instead
  - Places no-slip boundary mid-way between lattice points
  - Code for this currently commented out – can uncomment this section and comment out the on-grid bounce-back lines
- Can also add a submerged jet into the flow by using equilibrium forcing
  - Replace distribution functions with values calculated using `f_equ` function
    - Function inputs: lattice link `i`, velocity (`ux`, `uy`), `density`
  - Either set values in distribution function array `f` directly after propagation, or fix values (`ux`, `uy`, `rho`) for given point in `Calc_obs` subroutine

# Tutorial Exercise 1: Single component LBE simulations

## Ex3. Computational efficiency

- Most time-consuming parts of `CCP5_01.c` are:
  - Calculation of observables (`Calc_obs`)
  - Collisions (`Collide`)
- `Collide` subroutine calls `f_equ` function multiple times per grid point
  - Could in-line calculations of  $f_i^{eq}(\rho, \mathbf{u})$  directly into this subroutine instead of repeatedly calling this function for each lattice link
  - Alternatively, could change `f_equ` to calculate all local equilibrium distribution functions at a grid point in one go
- `Calc_obs` subroutine could also be optimised
  - HINT 1: Try assigning the distribution function `f[x][y][i]` to an intermediate variable before calculating `rho`, `ux` and `uy`
  - HINT 2: Multiplication is cheaper than division, so try calculating the reciprocal of `rho` for grid point and multiplying this into `ux` and `uy`

# Tutorial Exercise 1: Single component LBE simulations

## Ex4. Incompressible Navier-Stokes' fluids

- Change local equilibrium distribution function (mildly compressible form):

$$f_i^{eq}(\rho, \mathbf{u}) = t_i \rho \left[ 1 + 3(\mathbf{c}_i \cdot \mathbf{u}) + \frac{9}{2}(\mathbf{c}_i \cdot \mathbf{u})^2 - \frac{3}{2}u^2 \right]$$

to form for exactly incompressible liquids:

$$f_i^{eq}(\rho, \mathbf{u}) = t_i \rho + t_i \rho_0 \left[ 3(\mathbf{c}_i \cdot \mathbf{u}) + \frac{9}{2}(\mathbf{c}_i \cdot \mathbf{u})^2 - \frac{3}{2}u^2 \right]$$

- Density of fluid now constant,  $\rho_0$
- Uses  $\rho$  as variable density (analogue to pressure)
- Velocity now calculated as  $\mathbf{u} = \frac{\sum_i f_i \mathbf{c}_i}{\rho_0}$
- Either change `f_eq` function in copy of `CCP5_01.c` or use previously modified version (`EILBGK.c`)

# Tutorial Exercise 1: Single component LBE simulations

## Ex5. Viscous stress tensor

- Can be calculated at a lattice point using:

$$\sigma'_{\alpha\beta} = \frac{\rho c_s^2}{\omega} \sum_i (f_i^{eq} - f_i) c_{i\alpha} c_{i\beta}$$

- No need to find velocity gradients: big advantage of LBE over CFD
- Can be used to impose non-Newtonian and/or turbulent flows by finding shear rates and using these to set viscosities/relaxation times for each lattice point
- In lid-driven cavity system, bulk flow approximates potential flow (negligible viscous stress)
- Either modify `Calc_obs` subroutine in copy of `CCP5_01.c` to calculate and write file with  $\sigma'_{\alpha\beta}$  values or use previously modified version (`sigma.c`)

# Multi-component LBE algorithm

## Lishchuk's multi-component (chromodynamic) algorithm

- Two fluids: background fluid = blue, drop fluid = red
- Each fluid at each lattice point has its own distribution function ( $B_i, R_i$ ) and an 'achromatic' distribution function can be defined,  $f_i = B_i + R_i$

- Fluid densities at lattice points available:

- $\rho_B = \sum_i B_i$
- $\rho_R = \sum_i R_i$
- $\rho = \rho_B + \rho_R = \sum_i f_i$

- We define a 'phase index':

$$\rho^N = \frac{\rho_R - \rho_B}{\rho_R + \rho_B}$$

- Values of  $\rho^N$  range from +1 (entirely red) to -1 (entirely blue)
- Gradients of  $\rho^N$  in interfacial regions help us determine interfacial normals

$$\hat{\mathbf{n}} = \frac{\nabla \rho^N}{|\nabla \rho^N|}$$

Gradient calculations using lattice 'stencils', e.g.

$$\nabla \rho^N(\mathbf{x}) = \frac{1}{c_s^2} \sum_i t_i \rho^N(\mathbf{x} + \mathbf{c}_i) \mathbf{c}_i$$

# Multi-component LBE algorithm

## Lishchuk's multi-component (chromodynamic) algorithm

- Interfacial curvature available from spatial gradient of interfacial normal

$$K = n_x n_y \left( \frac{\partial n_x}{\partial y} + \frac{\partial n_y}{\partial x} \right) - n_x^2 \frac{\partial n_y}{\partial y} - n_y^2 \frac{\partial n_x}{\partial x}$$

- Force acting between red and blue fluids at interface:

$$\mathbf{F} = \frac{1}{2} \alpha K \nabla \rho^N$$

Interfacial tension  $\alpha$

- Force can be applied to fluids during collision step: several forcing schemes available, Guo forcing scheme recommended
- For continuity of tangential stresses and fluid velocity, need to carry out collisions and apply interfacial force to achromatic distribution functions (giving  $f'_i$ ), then segregate back out:

$$R'_i = \frac{\rho_R}{\rho} f'_i + \beta t_i \frac{\rho_R \rho_B}{\rho} \mathbf{c}_i \cdot \hat{\mathbf{n}}$$
$$B'_i = \frac{\rho_B}{\rho} f'_i - \beta t_i \frac{\rho_R \rho_B}{\rho} \mathbf{c}_i \cdot \hat{\mathbf{n}}$$

Segregation parameter  $\beta$  controls (non-zero) interfacial thickness, prevents 'pinning' of drop to lattice points

# Tutorial Exercise 2: Multi-component LBE simulations

## Ex1. Code familiarisation/Laplace law pressure step validation

- Notebook: [Day11LBETutorial2Ex1-3.ipynb](#)
- Another simple LBE code in C: `CCP5_02.c`
  - Models a static drop surrounded by background fluid in a periodic box using Lishchuk algorithm
  - Need to compile before running code using (GNU) C compiler, linking in some mathematics libraries:

```
gcc -o LBE CCP5_02.c -lm
```

- Run code with command-line option for number of timesteps ( $N$ ):

```
./LBE N
```

- Defaults to 10000 timesteps if  $N$  not specified
- Properties (e.g. drop radius,  $\alpha$ ,  $\beta$ ) hard-coded: re-compile for changes

# Tutorial Exercise 2: Multi-component LBE simulations

## Ex1. Code familiarisation/Laplace law pressure step validation

- Python scripts available in notebook to launch code, display progress bar and plot results written to files (properties at all lattice points):
  - Overall density  $\rho$
  - Phase index/field  $\rho^N$
  - Interfacial curvature  $K$
  - Velocity modulus  $|\mathbf{u}|$  - will not be zero due to ‘interfacial microcurrents’
- Further script available to find drop radius and find densities inside/outside drop – can confirm Laplace law holds and interfacial tension  $\alpha$  obtained:

$$p_R - p_B = c_s^2(\rho_R - \rho_B) = \frac{\alpha}{R}$$

# Tutorial Exercise 2: Multi-component LBE simulations

## Ex2. Fluid component segregation (re-colouring)

- Segregation parameter  $\beta$  given as `BETA_LKR` in `#define` line at top of `CCP5_02.c` code
- Try reducing this value and contrast/compare results:
  - Values of  $\rho^N$  around boundary should vary as a hyperbolic tangent profile
  - Interfacial width should be inversely proportional to  $\beta$
  - Microcurrent magnitudes should be inversely proportional to interfacial width
- What happens if  $\beta$  is increased?

# Tutorial Exercise 2: Multi-component LBE simulations

## Ex3. Curvature calculations

- Calculations of  $K$  currently fairly complicated, but could be simplified to divergence of interfacial normal, i.e.:

$$K = \frac{\partial n_x}{\partial x} + \frac{\partial n_y}{\partial y}$$

- Edit `calc_obs_2` in a copy of `CCP5_02.c` to use this definition
  - What happens to the microcurrents compared with the original code?
  - Can a stable solution still be obtained?

# DL\_MESO

## General purpose mesoscopic modelling software package

- Includes Lattice Boltzmann (LBE) and DPD codes (serial and parallel with MPI and/or OpenMP), Java GUI (optional)
- Created for CCP5 at UKRI STFC Daresbury Laboratory in 2004
  - Now developed for UKCOMES (EPSRC High-End Computing consortium)
- Free for academic use (licence on annual subscription for commercial use)
- Described in Molecular Simulation articles:
  - Seaton *et al.*, *Mol Sim* **39** (10), 796–821 (2013)
  - Seaton, *Mol Sim* **47** (2–3), 228–247 (2021)
- Copy of beta version (2.8) included with course materials, available for you to take home with you
  - Small additions included for exercises (makefiles in working directory, additional Python scripts)

# Tutorial Exercise 2: Multi-component LBE simulations

## Ex4. Equilibration dynamics with DL\_MESO\_LBE

- Notebook: [Day11LBETutorial2Ex4-5.ipynb](#)
- Switching over to LBE code in DL\_MESO
  - Includes Lishchuk multi-component algorithm used in `CCP5_02.c` plus some extensions (will use one of these later)
- Makefile available to compile DL\_MESO\_LBE with OpenMP multithreading
- Python script available to launch in notebook
- Modelling drop subjected to linear shear flow
  - Using fixed velocity boundary conditions at top and bottom of box
  - Shear only applied after drop given time to equilibrate

Different options for implementing fixed velocity boundary conditions: default in DL\_MESO\_LBE based on bounce back of non-equilibrium distribution functions (Zou-He)

# Tutorial Exercise 2: Multi-component LBE simulations

## Ex4. Equilibration dynamics with DL\_MESO\_LBE

- Input files for DL\_MESO\_LBE:
  - Simulation controls in **lbin.sys** (right)
  - Boundary conditions in **lbin.spa**
  - Initial conditions in **lbin.init**
- Relevant keywords in **lbin.sys** file:
  - **collision\_type** (also forcing type)
  - **interaction\_type**
  - **total\_step**
  - **equilibration\_step**
  - **save\_span**
  - **speed\_top\_0** ( $u_x$  at top boundary)
  - **speed\_bot\_0** ( $u_x$  at bottom boundary)
  - **interaction\_0\_1** ( $\alpha$ )
  - **segregation** ( $\beta$ )

# Tutorial Exercise 2: Multi-component LBE simulations

## Ex4. Equilibration dynamics with DL\_MESO\_LBE

- Segregation works slightly differently in DL\_MESO\_LBE cf. CCP5\_02.c, e.g.

$$R'_i = \frac{\rho_R}{\rho} f'_i + \beta t_i \frac{\rho_R \rho_B}{\rho^2} \mathbf{c}_i \cdot \hat{\mathbf{n}}$$

- Apart from changing value of  $\beta$ , will give identical results to previous code
- Run calculation with supplied input files
  - DL\_MESO\_LBE generates structured grid VTK files as outputs with densities and velocities at lattice points
  - Output files can be read using ParaView (all at once) or by Python scripts supplied with notebook (individually)
    - Filters available in ParaView to calculate additional properties (e.g. phase indices  $\rho^N$ ) from those supplied, plot streamlines etc.

# Tutorial Exercise 2: Multi-component LBE simulations

## Ex4. Equilibration dynamics with DL\_MESO\_LBE

- Reynolds' and capillary numbers available for drop in linear shear flow:

$$Re = \frac{R^2 \dot{\gamma}}{\nu}$$
$$Ca = \frac{\rho \nu U}{\alpha} = \frac{R \rho \nu \dot{\gamma}}{\alpha}$$

$$\dot{\gamma} = \frac{u_x^{\text{top}} - u_x^{\text{bottom}}}{L_y}$$
$$= \frac{\partial u_x}{\partial y}$$

- Vary wall velocities (shear rate) and interfacial tension
  - Should be a capillary number (or set of capillary numbers?) that cause the drop to break up due to the flow
- First output file (`1bout000000.vts`) gives equilibrated state before shear is included
  - Can examine microcurrent magnitudes with varying  $Ca$

# Tutorial Exercise 2: Multi-component LBE simulations

## Ex5. Changing Lishchuk algorithm to ‘Spencer tensor’

- DL\_MESO\_LBE has variety of multi-component algorithms based on Lishchuk’s original
- One form (‘Spencer tensor’) replaces calculation of interfacial forces with direct forcing terms applied during collision stage:

$$F_i = \frac{t_i \beta \alpha \omega \rho_B \rho_R}{c_s^4 \rho^3 \Delta t} (\hat{\mathbf{n}}\hat{\mathbf{n}} - \mathbf{I}) : (\mathbf{c}_i \mathbf{c}_i - c_s^2 \mathbf{I})$$

- No longer need to calculate curvature (from gradients of interfacial normals)
  - Fewer core-to-core MPI communications when running on multiple processors
- Still need interfacial normals and thus phase index gradient calculations
  - Local phase index gradients calculations possible distribution functions directly – not being used here but also available in DL\_MESO\_LBE, makes Lishchuk algorithm fully localised to each lattice point

# Tutorial Exercise 2: Multi-component LBE simulations

## Ex5. Changing Lishchuk algorithm to 'Spencer tensor'

- Start by modifying `lbin.sys` from previous calculation to use Spencer tensor variant – change these lines:

```
collision_type      BGKGuo
interaction_type     Lishchuk
```

to

```
collision_type      BGK
interaction_type     LishchukSpencerTensor
```

- Check microcurrents for a given interfacial tension and shear rate
  - Spencer tensor variant likely to give larger spurious microcurrents, but not by much

# Tutorial Exercise 2: Multi-component LBE simulations

## Ex5. Changing Lishchuk algorithm to 'Spencer tensor'

- Another set of input files for a three-component system with linear shear: background fluid and two immiscible drops
- Initially placed drops too close together so they overlap
  - Segregation should separate them out during equilibration
  - Higher interfacial tension between fluids in drops to prevent them getting too close together
- Try this simulation with both original Lishchuk method and Spencer tensor variant
  - What has happened to the drops during equilibration?
  - What happens afterwards when shear is applied?
  - Why do the two (otherwise similar) approaches give different results?

# Before you finish ...

## Registering for DL\_MESO

- If you want to use DL\_MESO for your own research (either DPD or LBE), please register via the website

[www.ccp5.ac.uk/DL\\_MESO](http://www.ccp5.ac.uk/DL_MESO)

## DL\_Software Digital Guide

- If you want more information about DL\_MESO, the mesoscale modelling methods it includes and/or other DL\_Software packages, we have an online guide available at

<https://dl-sdg.github.io/>
